Abstract

To keep up job search motivation and maintain re-employment chances, it is important that unemployed individuals do not stop believing in their ability to (re)gain satisfying employment. This article examines whether further education during unemployment has a positive effect on perceived employability (i.e. the subjective assessment of one's chances to obtain the desired job), based on a panel survey of unemployed young adults in Austria. The article finds that educational activities – either on own initiative or as part of an active labor market program – indeed help to sustain or even increase perceived employability. However, only for long-term programs do the effects persist beyond the duration of the activity. This study thus identifies substantial psychological side effects of active labor market policies involving further education, which could be used to increase actual employability.

Keywords

Active labor market policies, employability, further education, unemployment, youth

Introduction

The high level of youth unemployment in many countries is one of the challenges of our time. If young adults experience prolonged periods of unemployment and unsuccessful job search activities early in their career, they may lose faith that they will ever find

adequate employment (Fryer, 1997; cf. Schmillen and Umkehrer, 2013). This lack of faith, in turn, may result in reduced motivation for job search and detachment from the labor market, thereby becoming a self-fulfilling prophecy (Chen and Lim, 2012; cf. Steiber, 2013). Hence, it is important that the young unemployed do not stop believing in their abilities to find a job.

The ability to (re)gain suitable employment can be subsumed under the term ‘employability’. Employability has become somewhat of a buzz-word in the political discourse and is stressed in diverse strategy papers concerning active labor market policies. Recommendations on fostering employability have, for example, been central to UN and OECD reports (e.g. OECD, 1994; UN, 2001), part of the UK’s New Deal program (DfEE, 1997), and a basic component of the EU’s 2020 strategy (European Commission, 2010). The recommendations emphasize the role of education in enhancing employability, as higher levels of education are associated with a lower risk of unemployment, shorter transition periods between jobs, higher wages, etc. (see e.g. Becker, 1993). In response, several countries have reformed their active labor market policies (ALMPs) in order to provide the unemployed – especially young unemployed – with additional qualification or training opportunities. However, evidence in regard to the effects of such further education programs on employability of the unemployed is rather scarce and ambiguous (Card et al., 2010; Crépon and van den Berg, 2016), particularly in regard to the target group of young adults (Card et al., 2017). The mechanisms behind potential effects are not yet completely understood. Our study addresses this gap in the literature by focusing on potential psychological mechanisms.

As stressed above, what matters for motivational aspects – which are essential during job search – is not necessarily the actual employability of the individual, but how the individual perceives his or her own situation (Berntson et al., 2006). In the present article, we thus study perceived employability (specifically: the subjective chances of obtaining the desired job) among young unemployed aged 18–28 in Austria. Using panel data gathered at the beginning of an unemployment spell (t_0) and one year after (t_1), we test which factors are crucial in promoting or at least keeping up perceived employability in times of unemployment, with a specific focus on further education. In line with the previous literature, we find that individuals with higher levels of formal education report higher levels of perceived employability. In addition, we detect significant effects of further education during the period t_0 – t_1 . Individuals who participated in education or ALMP training activities at the time of the second interview displayed higher levels of perceived employability than those in NEET status (not in education, employment or training) or even those who found a job between the two interview dates.

Our study thus offers new insights on the effects of ALMPs from which we can deduce concrete policy recommendations. Moreover, we shed light on the factors behind perceived employability, a concept which has been found highly relevant not only for job search and career success, but also for mental health and general well-being (Berntson and Marklund, 2007; Green, 2011). We focus on young people, a group which is particularly vulnerable in terms of labor market participation and prone to lasting scarring effects from unemployment experience at early career stages (Klug, 2017). ALMP policies involving further education are especially targeted towards young adults (see, for example, the European Union’s Youth Employment Initiative and the Youth Guarantee).

Hence, from a practitioner's point of view, it is important to analyze the effectiveness of this approach. Furthermore, from a methodological point of view, it is helpful to analyze different age groups separately, as educational activities may differ considerably between groups.

The article proceeds as follows. First, we review the literature on employability in order to define the term 'perceived employability' for the purpose of this article. Next, we discuss which factors may affect perceived employability. Thereafter, we present our data and descriptive analyses of the dependent and the main independent variables. We then use regression models to test the hypotheses. In the conclusion, we discuss our results, their implications for ALMPs, and potential avenues for future research.

Defining perceived employability

We rely on the definition of employability applied by Hillage and Pollard (1998: 2): 'While there is no singular definition of employability, a review of the literature suggests that employability is about work and the ability to be employed; i.e. the ability to gain initial employment [...], maintain employment [...], and obtain new employment if required [...]. It is also, ideally, about the quality of such work or employment. People may be able to obtain work but it may be below their level of skill, or in low paid, undesirable or unsustainable jobs.' Put differently, employability is '[t]he ability to keep the job one has or to get the job one desires' (Rothwell and Arnold, 2007: 25).

Although this definition is widely applied, the term 'employability' has become blurred by its use in different contexts. In the political discourse as well as in some scientific studies, employability mainly refers to the individual's employability skills. Researchers have identified a multitude of factors that relate to the ability of (re)gaining employment, such as human and social capital, adaptability, attitudes towards work and self-efficacy. These personal qualities are sometimes equated with employability (see e.g. Fugate et al., 2004). Other researchers, however, have criticized this approach for focusing solely on the supply side (Brown et al., 2003; McQuaid and Lindsay, 2005), arguing that it is not just the labor supply side, but also the demand side that affects the labor market chances of individuals. Thus, if someone has difficulties finding employment, the 'problem' does not solely reside with the individual, but can also be due to structural constraints (e.g. economic conditions) or a mismatch between supply and demand (McQuaid and Lindsay, 2005). Hence, while the certain characteristics of the individual may crucially affect employability, they do not equal it (Hillage and Pollard, 1998). In the present article, individual assets are therefore treated as preconditions of, but not equated with employability.

Employability has been studied in different contexts and the terminology has been adapted to the subject at hand. One major strand of research has looked into school-to-work transitions and the employability of graduates (e.g. Okay-Somerville and Scholarios, 2017; Pinquart et al., 2003). A second strand has focused on the unemployed and their chances of re-entering the labor market (Koen et al., 2013; McArdle et al., 2007; Westaby and Braithwaite, 2003). A third strand has studied employability among employed individuals, for example in contexts of job insecurity (Anderson and Pontusson, 2007; Wittekind et al., 2010) or building on the concept of boundary-less careers, which

assumes that switches between jobs, employers and occupations are an inherent part of today's employment histories (e.g. Eby et al., 2003). While the first two strands of research (on graduates or the unemployed) mainly study objective employability, especially the third strand (on employees) is predominantly concerned with perceived employability.

In contrast to objective employability, which relates to how easy (or difficult) it is, in reality, to obtain initial or new employment which is sustainable and satisfactory (Okay-Somerville and Scholarios, 2017; Saks and Ashforth, 1999), perceived employability relates to how easy (or difficult) one *believes* it will or would be to find satisfying employment if necessary (Berntson, 2008: 11). Perceived employability may thus differ from objective employability, as there is no guarantee that one's evaluation is realistic (Hogan et al., 2013). This, however, does not render perceived employability an empty concept. To the contrary, as postulated by the Thomas theorem, the perception of a situation can be more important for shaping behavior, feelings and thoughts than the situation itself (Katz and Kahn, 1978; Lazarus and Folkman, 1984; Thomas and Thomas, 1938). Perceived employability has been shown to positively affect health (Berntson and Marklund, 2007) and self-esteem (McArdle et al., 2007). Moreover, perceived employability shows a moderating effect on the relationship between job insecurity and general well-being (Silla et al., 2008). Perceptions can thus influence the actual situation insofar as health, self-esteem and well-being are positively related to objective employability (Berntson, 2008: 11). Furthermore, perceived employability supposedly has an impact on the intensity of job search activities. Social cognitive theory stipulates that whether someone perceives goal attainment within reach or not affects behavior. According to this line of argumentation, perceived employability should stimulate search activities (cf. Pinquart et al., 2003). However, one could also conceive of the reverse relationship: overconfidence may result in lower effort (Vancouver et al., 2002). For unemployed individuals, McArdle et al. (2007) establish support for the first assumption. Using longitudinal survey data from Australia, they find that higher levels of perceived employability are related to increased job search activities. As job search activities are positively correlated with the probability of finding new employment, higher levels of perceived employability may result in higher levels of objective employability (Wanberg et al., 2010). To sum up, perceived employability is not just a weak measure of objective employability, but a factum in itself, which crucially affects the future career and well-being of individuals.

An important component of perceived employability as defined above is the quality and desirability of the job one perceives to be able or unable to obtain. The prospect of working in the desired occupation should stimulate job search activities and well-being to a greater extent than the prospect of a job which is not attractive. We thus study 'perceived employability in the desired occupation' as the outcome of interest in this article. In doing so, we offer a new perspective on perceived employability. To date, empirical research on perceived employability has not accounted for the aspect of job quality. Furthermore, in contrast to prior studies, we do not study perceived employability among employees, but among individuals who recently became unemployed. Using a longitudinal design, we also study how this perception changed in the first year after becoming unemployed, when some of the respondents were still searching for a job while others

were employed, or engaged in education or training activities. We first look at the effects of education and other individual-level factors on perceived employability at the beginning of an unemployment spell. Then, we test whether further education affects the change in perceived employability during and after a period of unemployment.

Individual-level determinants of perceived employability

In the present study, we focus on the individual-level determinants of perceived employability. We follow Berntson (2008: 23–29), who distinguishes between the following individual resources that supposedly affect perceived employability: knowledge and skills, social capital, attitudes, dispositions and demographics.

Knowledge and skills are the most commonly referred to individual resources and thus constitute the focus of our study. Especially formal education is generally assumed to be among the most important factors behind labor market success. Its influence on objective employability has been widely established (Becker, 1993). In regard to perceived employability, in a study on hospitality and tourism workers from Greater London, Croucher et al. (2018) find support for a positive effect of education. In addition, using data from the fifth wave of the European Social Survey on employed individuals who were asked to evaluate how difficult or easy it would be for them to get a similar or better job if they had to leave their current job, Berglund and Wallinder (2015) also show that education positively affects perceived employability.

However, what happens if unemployed individuals (i.e. those who register at the public employment service in the aim of obtaining a job) start to engage in further education, either by taking up some sort of formal education (e.g. vocational training or academic studies) or in terms of specific occupational skills training courses (e.g. as part of active labor market programs)? In addition to the skills an individual already possesses, the individual's capacities, i.e. the willingness and capability to develop new skills and to educate him- or herself, are supposed to be of importance for employability (Fugate et al., 2004). Yet, studies evaluating the effect of further education or training activities during unemployment (mostly in the context of ALMPs) have provided mixed results (Card et al., 2010). While some evaluations of specific programs have found evidence for a positive effect on employability, others have not been able to detect any effects, and sometimes even temporary negative 'locking-in' effects were discovered. An overall positive effect of ALMP training activities on labor market success is difficult to identify, as there is usually no random selection into these activities; rather, it is especially the most vulnerable individuals who participate in ALMP trainings. Consequences of further education on perceived instead of objective employability have – to the best of our knowledge – not yet been tested.¹ However, Creed et al. (2001) have shown that occupational skills training courses affect the level of self-efficacy. Moreover, Koen et al. (2013) find positive effects of re-employment interventions on the self-evaluation of employability skills such as human capital, adaptability and career identity. We therefore assume that further education – whether on own initiative or as part of ALMPs – also increases perceived employability in the desired occupation.

Apart from knowledge and skills, social capital is supposed to be an important factor behind employability (Fugate et al., 2004). Social capital is defined as the social structure

that facilitates individual actions (Coleman, 1988), in our case finding employment. This social structure comprises of social relations and networks that prove useful when searching for jobs, by conveying information about job opportunities and linkages to potential employers (Freitag and Kirchner, 2011; Granovetter, 1973). Attitudes towards work may also influence employability, because they affect the motivation to seek work, explore different possibilities, and adapt to constantly changing work situations (Eby et al., 2003). Individuals who place more importance on work and show strong career aspirations are supposed to do better in finding a new job if necessary (Fugate et al., 2004). Furthermore, employability is supposed to be influenced by individual dispositions, such as neuroticism, affectivity, locus of control, self-esteem and self-efficacy. Of these intertwined and partially overlapping factors, especially self-efficacy, i.e. 'beliefs in one's capabilities to mobilize the motivation, cognitive resources and courses of action needed to meet given situational demands' (Wood and Bandura, 1989: 408), is deemed to be of special importance. Self-efficacy in adolescence has, for instance, been shown to have long-term effects on unemployment and job satisfaction in adulthood (Pinquart et al., 2003).

Socio-demographic factors may also affect (perceived) employability. Women, especially mothers of small children, tend to experience greater difficulty in finding suitable employment than men. In addition, men are on average more optimistic and tend to perceive better opportunities than women (Berglund and Wallinder, 2015). Concerning age, both young adults at the beginning of their careers and older individuals at the end of their working life are more at risk of experiencing difficulties in finding (new) employment. As for perceived employability, younger individuals typically assess their chances in the labor market more favorably than older ones, who tend to worry more about job insecurity (Dixon et al., 2013). This finding, however, pertains to the broad group of individuals of working age while our study specifically focuses on young adults. Within this group, predictions are more difficult. On the one hand, the youngest who are about to start their career may have unrealistically high expectations. On the other hand, they may (realistically) be more pessimistic about their job opportunities compared to more experienced individuals. Thus, both positive and negative effects of age are conceivable. Finally, individuals with a migrant background often find it difficult to get a job and sometimes feel discriminated against, potentially resulting in lower levels of perceived employability (Berglund and Wallinder, 2015). Surprisingly, however, Wallinder (2018) detects a positive effect of being born in a foreign country on the subjective assessment of re-employment prospects.

In the following analysis, we will focus on the effect of *further* education on the perceived employability of young adults who recently became unemployed. To this end, we study changes in perceived employability in the year after the start of the unemployment spell. We test whether further education (either as part of an ALMP training or completely voluntarily, self-organized and self-funded) during this period had a positive effect, leading to an increase or at least a smaller decrease in perceived employability in times of unemployment. Thereby, we distinguish between education as part of an ALMP training on the one hand and self-organized and -funded education on the other hand, assuming that voluntary activities which require greater personal investments will have a greater effect on perceived employability, as they are on average more positively evaluated by participants (Steiber et al., 2017). Moreover, we distinguish between ongoing

and past education in order to study whether potential effects on perceived employability wear off when the young adults leave the supportive environment of the program and return to NEET (not in education, employment, or training) status or to a job which does not suit them (cf. Andersen, 2008). Finally, we distinguish between short-term and long-term educational activities, assuming that length should positively affect perceived employability, as it has been found to increase actual employability (Card et al., 2010).

Hypothesis: Further education in the period t_0 – t_1 positively affects the change in perceived employability between t_0 and t_1 , especially if (a) the educational activity is self-organized (in contrast to being part of an ALMP), (b) the educational activity is still ongoing, and (c) the educational activity is of longer duration.

Data and variables

To test our hypotheses, we draw on panel survey data from Austria (Mühlböck et al., 2018; Steiber et al., 2017). In summer 2014, we conducted a survey among young adults aged 18–28 who had recently become unemployed (and registered at their local public employment service up to four weeks before the interview date). Respondents were recruited to participate in the survey at the public employment service in Vienna. The survey was self-administered; questionnaires were filled in on laptops by the respondents, but in the presence of interviewers. Respondents who were willing to participate in the follow-up interview were asked to provide their contact details. One year later, these young adults were contacted again to participate in the second wave of the survey, which was again self-administered and computer-assisted. At the time of the second interview, many respondents were still (or again) searching for a job (46%), whereas others were in education or had found new employment. Many questions, like for example the question on perceived employability, were asked at both the first (t_0) and the second interview (t_1) in order to be able to identify changes over time. In the first wave, our sample comprised of 1215 18- to 28-year-olds in Vienna who became unemployed during the observation period. In the second wave, we achieved a re-interview response rate of 51%, i.e. 625 persons participated in both waves. This response rate equals the response rate of the IZA evaluation dataset which was collected based on a similar design but covers a wider age range (16–54 years old) of newly unemployed individuals (Arni et al., 2014). Our panel comprises only of young adults, who constitute a particularly difficult and mobile target group. In order to correct for non-response and attrition bias, we computed weights. For the first wave, weights were calculated based on exact information about the combined distribution of the variables age, sex and education in the basic population (i.e. the inflow into registered unemployment in the age group 18–28 in Vienna in summer 2014) based on register data. For the second wave, we were able to incorporate further individual characteristics (socio-demographics, personality traits, costs in terms of time and cognitive burden, and readiness as well as ability to participate) based on the information gathered in the first wave in our weights. We calculated propensity scores based on the estimated probability of first wave participants to also participate in the second wave and combined them with the first wave post-stratification weights (for detailed information on sample selection, survey implementation and the weighting procedure, see Mühlböck

Figure 1. Histograms of perceived employability at t_0 and change in perceived employability between t_0 and t_1 .

Note: n (perceived employability at t_0) = 992, n (change in perceived employability between t_0 and t_1) = 446.

et al., 2018). Importantly, no major changes in ALMPs directed towards young adults occurred in Austria between the first and the second survey wave.

The dependent variable, perceived employability (*PE*), was measured at both t_0 and t_1 . First, respondents were asked to name their desired occupation. Those who indicated their preferred occupation (992 of the first wave and 507 of the second wave respondents) were then asked to rate the probability of becoming employed in this occupation in the future.² The answer scale ranges from 0 (= extremely unlikely) to 10 (= extremely likely), which was recoded to a scale from 0 to 1 for the following analysis. The operationalization reflects our focus on the quality of the potential employment (Hillage and Pollard, 1998; Rothwell and Arnold, 2007). In contrast to questions about how long it might take to find new employment or the likelihood of finding employment within a given time span, this kind of question can be applied to both employed and unemployed individuals. This is important, as some participants of the second wave had found (and kept) employment (not necessarily in their desired occupation) in the year after the first interview, while others were still (or again) unemployed at t_1 . The question also applies to respondents who already worked in their desired occupation when participating in the second wave, as they could simply pick the highest value. The difference between *PE* at t_1 and *PE* at t_0 was calculated for each respondent and denoted *change in PE*. Hence, if a respondent displayed a lower *PE* at t_1 than at t_0 , *change in PE* has a negative sign. Figure 1 displays the distributions of *PE* at t_1 and *change in PE*. As can be seen, *PE* at t_1 was rather high with an average value of 0.72 and about a third of respondents picked the highest value. Between t_0 and t_1 , *PE* decreased on average by 0.04 to 0.68. While 29% of the respondents reported higher levels of *PE* at t_1 than at t_0 , for 27% *PE* neither increased nor decreased, and 44% reported lower levels of *PE* at t_1 than at t_0 .

Concerning *formal education*, we distinguish between four different levels according to the International Standard Classification of Education (ISCED) of 1997:³ ISCED 0-2 (primary or lower secondary education), ISCED 3B (higher secondary education), ISCED 3A-4 (higher secondary education and post secondary education), and ISCED 5-6 (tertiary education, i.e. university degree or similar). The level of formal education is rather low in our sample (especially at t_0), which accurately reflects the distribution of the variable in the population of young unemployed, as can be seen in Table A1 in the Appendix.

In this study, we are primarily interested in whether participating in some sort of educational activity between t_0 and t_1 or at t_1 affects the change in PE. The variable *ALMP training in t_0 - t_1* measures if re-employment training was received during this period. ALMP trainings are assigned by the case workers in the public employment service, preferably to those young adults with a high probability of long-term unemployment. Hence, participation is usually not voluntary. Of the 625 second wave respondents, 34% had taken part in ALMP training in t_0 - t_1 but already finished before t_1 , while 5% were still in training at the time of the second interview (t_1); 31% of the respondents received short-term trainings of three months or less, while 9% participated in long-term activities of more than three months. The variable *Education in t_0 - t_1* denotes whether a respondent participated in any educational activities besides ALMP re-employment trainings (this was the case for 41% of the respondents in our sample, with some individuals participating in both ALMP training and a self-chosen educational activity in the period under review).⁴ Such further education comprises of vocational training (as part of the dual educational track), secondary school, tertiary education, or some sort of (non-formal) specific occupational training (e.g. training for massage therapist, accounting). The unemployed usually self-organize the educational activity (but can be supported by case workers) and may apply to the public employment service for funding if necessary. We distinguish between past further education (if someone is no longer in education at t_1 , as was the case for 11% of the respondents), and current further education (if someone is still in education at t_1 , as was the case for 30% of the respondents). In addition, we account for the length of the educational activity (three months or less: 11%, more than three months: 30%).

In the regression analyses, we control for a number of further factors, which – as outlined in the theory section – have been found to affect (perceived) employability: number of friends (as an indicator for social capital), work centrality, self-efficacy, past labor market experience as an indicator for relevant skills (*work experience*, measured as the number of years previously employed) and socio-demographic characteristics like gender, age and migration background (cf. Berntson, 2008: 23–29). Details on the exact model specifications are given in the next section. Further information concerning the measurement of all variables is provided in the Appendix.

Analysis

As a first step, we test the effect of formal education on perceived employability among young unemployed. We estimate fractional logistic regression models with *perceived employability at t_0* as the dependent variable (see Table 1).⁵ The first model

Table 1. Fractional logit regression on estimated probability of becoming employed in the desired occupation (PE) at t0.

only includes the dummy variables for the different educational levels, while the second model controls for other potentially influential variables. Both regression models are weighted using the weights for the first wave data as described in the last section (t0 weights).⁶

The regression analysis supports previous accounts in the literature regarding a positive effect of formal education. The higher the educational level completed, the higher the perceived employability. Further factors which prove to be of influence are work centrality and self-efficacy, while for example the number of friends, socio-demographic factors and the extent of previous work experience do not exhibit any notable effects in our model.⁷

The effect of further education on the *change in* perceived employability between t0 and t1 is tested using a lagged dependent variable approach (Grill, 2017), i.e. we employ similar models as for the effect of education on perceived employability at t0, but now with perceived employability at t1 as the dependent variable, while controlling for the level of perceived employability at t0. This is equivalent to a model with change in perceived employability as the dependent variable controlling for perceived employability at t0 (i.e. a conditional change score model; Berrington et al., 2006). We include measures for education in the period from the first interview until the second, our main independent variables of interest. In Model 1 in Table 2, we distinguish between ALPM

trainings and other types of further education. In Model 2, we further differentiate between current and past as well as short-term (≤ 3 months) and long-term (> 3 months) educational activities. In both models, we include controls for demographic characteristics, number of friends, work centrality and work experience. Like the regression models for *perceived employability at t0*, the regressions on *perceived employability at t1* are weighted, this time using the panel weights for the second wave (t1 weights).⁸

Figure 2. Predicted values for perceived employability at t1 dependent on whether someone participated in some form of ALMP training or further education in the period t0–t1. Note: Results based on Model 2 in Table 2.

In Model 1, we do not find a significant positive overarching effect of ALMP training, but we do find one for other educational activities in the period t0–t1. However, Model 2 offers further important insights, which are illustrated in Figure 2. As can be seen, whether an ALMP training was still ongoing at t1 or already concluded made an important difference. Ongoing ALMP trainings have a statistically significant as well as sizable effect on perceived employability, notwithstanding whether they were short or long. For individuals who participated in an AMLP training activity at the time of the second interview, perceived employability at t1 was on average over 20% higher than for individuals who received no ALMP training. For those currently participating in a training activity, employability on average increased compared to t0, while decreasing for those who received no training or had concluded a short-term training before t1. Hence, the effect of current participation does not translate into a general significant effect of ALMP measures, as most respondents had already concluded their training at the time of the second interview – either returning back to NEET status, or to the labor market. In regard to other educational activities than ALMP trainings, the results indicate that duration is highly important for their effect on perceived employability. While the effect is not as strong as for ALMPs (just over 10% higher perceived employability for individuals participating in long-term activities compared to those who did not receive any further education in t0–t1), it does spill over to a general effect of educational (non-ALMP) activities, because most of these activities lasted for more than three months.

The control variables (including the level of formal education) do not have any significant effects, indicating that they only influence perceived employability at t0, and do not affect the change in the dependent variable between t0 and t1.⁹ Furthermore, controlling for the fact whether someone actually found a job in t0–t1 does not affect the results for ALMP training and further education (see Table A4 in the Appendix).

To sum up, we find support for the hypothesis that further education has a positive effect on the change in perceived employability and that this effect is on average stronger for self-organized educational activities than for ALMP trainings. We also find that duration matters – at least for education outside of ALMPs. For ALMP programs, there is a strong positive effect, which, however, is restricted to the duration of the program. This could also be due to the fact that ALMP trainings rarely last longer than three months.

Conclusion

Our study shows that education is closely linked to perceived employability among young adults with recent unemployment experience. Using data from an Austrian panel study on a sample of 18- to 28-year-olds who just became unemployed, we find that individuals with higher education perceived better chances to someday work in their desired occupation than those with low levels of formal education. Importantly, we also observe a positive effect of further education on changes in perceived employability in the year after becoming unemployed. On average, perceived employability declined during this period. However, if a person participated in further education (either on own initiative or as part of an active labor market program), his or her confidence to find suitable employment increased. However, we also find that the positive effects of the often short-term ALMP trainings wear off soon: someone who had participated in such an activity between the two interview waves, but was not doing so any longer at the time of the second interview, does not experience a significantly different change in perceived employability compared to someone who had not received any ALMP training. For other forms of further education, such as for example vocational training, schooling, or university studies, the effect depends not so much on whether the educational activity is still ongoing, but rather on the duration of the activity. For long-term education (i.e. more than three months), we find significant positive effects on the change in perceived employability.

As higher perceived employability may give rise to higher objective employability (Chen and Lim, 2012), our results are not only of importance for scientific research, but also for policy-makers. We offer empirical evidence for a positive effect of further education for young unemployed. Even the often spited re-employment trainings have the potential to boost the beliefs of young unemployed adults in their chances to find employment in their desired occupation – at least for the duration of the ALMP action. If this momentum of augmented optimism can be turned into increased motivation for job search and higher confidence displayed in job interviews, this may be an important avenue through which employment trainings offered by the public employment service can positively affect re-employment chances. At the same time, our findings indicate that voluntary and self-organized further education yields stronger effects on perceived employability than classic ALMP actions. Hence, such activities should be encouraged by case workers in the public employment service and funding opportunities should be expanded, especially because – as our results show – in order to be effective in the long run, educational activities should last at least a couple of months. Thereby, possible locking-in effects of such activities should of course be considered. However, if perceived employability indeed fosters search motivation and self-confidence, such locking-in effects can be offset by the increase in objective employability (cf. Card et al., 2017 on the positive effect of training programs in the medium and long run). Using the time during unemployment for

further education and skill-acquisition may even help to reduce the scarring effects on the later career of young adults.

While this study provided evidence on the determinants of perceived employability in periods of unemployment, there is still much room for future exploration of the topic. First, while we focused on Austria, there is little reason why our results should not apply to other countries as well. Comparative research could, however, investigate potential differences caused by educational systems, labor market regimes or between coordinated and liberal market economies. Furthermore, as our findings do not necessarily pertain to young adults only, future research should explore potential effects of further education on older individuals. Additional potentially influential factors, e.g. effects of constraints/opportunities like sectoral labor market conditions or individual resources like cognitive abilities, are worth studying. Moreover, future research could strive to assess the relationship between perceived and actual employability. Finally, comparisons between employed and unemployed samples would also be of interest.

Declaration of conflicting interests

The authors declared no potential conflicts of interest with respect to the research, authorship, and/or publication of this article.

Funding

The study is based on data from a panel survey which has been funded by the Austrian Federal Ministry of Labour, Social Affairs and Consumer Protection as part of the JuSAW project. Work on the article has been carried out as part of the CUPESSE project, which received funding from the European Union's Seventh Framework Programme for research, technological development and demonstration under grant agreement no. 613257.

Notes

1. At least not regarding perceived employability as defined above.
2. Original question wording: 'Wenn Sie an Ihre Zukunft denken, für wie wahrscheinlich halten Sie es, dass Sie Ihren Wunschberuf irgendwann ausüben werden?' ('Thinking about your future, how likely do you think it is that you will (ever) be employed in your desired occupation?')
3. For Austria, the ISCED 1997 classification has the advantage that it distinguishes between 'dual-education', i.e. a mix of school-based education and vocational training for which Austria (along with Germany) is famous, (3B) and general higher secondary education (3A and 4), a distinction that was lost in the newer ISCED 2011 classification.
4. Employment courses thereby do not count as further education to ensure that the two variables do not overlap.
5. Fractional logistic regression is used because the variable is bounded between 0 and 1. However, OLS regression models provide highly similar results (see Tables A2 and A3 in the Appendix).
6. However, results do not change when using unweighted regression.

7. The fact that work experience does not significantly affect perceived employability at t0 may appear surprising. One explanation could be that those with little work experience may instead estimate employability based on their perceived qualification.
8. Again, the main results do not change when using unweighted regression models.
9. We also tested for potential interaction effects between the level of formal education and further education. However, we find that the level of formal education has no impact on the effect of further education on perceived employability, i.e. individuals profit from further education irrespective of the level of formal education they had already achieved at t0.

Author biographies

Monika Mühlböck is a postdoctoral researcher at the University of Mannheim. Her research interests include labor market policy, political representation, EU politics, and survey methodology. A recent publication in *Political Behavior* analyzed the effects of expected downward mobility on political attitudes.

Nadia Steiber is a senior researcher at the Institute for Advanced Studies in Vienna. Her current research interests are in labor market inequality, intergenerational social mobility, and health from a life course perspective. Her most recent publication in *Social Science & Medicine* was concerned with the health implications of intergenerational educational mobility.

Bernhard Kittel is professor of economic sociology at the University of Vienna. His current main research interests are justice attitudes, group decision making, and marginal groups on the labor market. His work has been published in *Plos One*, *Social Science Research*, *Journal of Public Economics*, *Political Research Quarterly*, *AAPSS Annals* and *Sociological Inquiry*.

Appendix

Description of variables used in the regression models in alphabetical order.

- *Age*: measured in years
- *ALMP training in t0–t1*: indicates whether someone participated in an active labor market program at the time or the second interview (= current), did participate in such a program between the first and the second interview (= past), or did not participate in such a program between t0 and t1 or at t1 (= none).
- *Education in t0–t1*: indicates whether someone participated in some sort of educational activity (which was not part of an active labor market program) at the time or the second interview (= current), did participate in such an activity between the first and the second interview (= past), or did not participate in such an activity between t0 and t1 or at t1 (= none).
- *Found job in t0–t1*: indicates whether someone found a job between t0 and t1 (thereby, vocational training and marginal employment, i.e. a monthly salary below 406€, does not qualify as a job).
- *Formal education*: four different levels of formal education according to the International Standard Classification of Education (ISCED) of 1997: ISCED 0-2 (primary or lower secondary education, i.e. ‘Pflichtschulabschluss’ or lower), ISCED 3B (higher secondary education, i.e. ‘Lehre’ or ‘Berufsbildende Mittlere Schule’), ISCED 3A-4 (higher secondary education and post secondary education, i.e. ‘Allgemeinbildende Höhere Schule’ or ‘Berufsbildende Höhere Schule’), and ISCED 5-6 (tertiary education, i.e. university degree or similar).
- *Gender*: 1 = female, 0 = male
- *Migration background*: distinguishes between no migration background, migrants of the second generation (i.e. born in Austria but none of the parents from Austria), and migrants of the first generation (i.e. not born in Austria and none of the parents from Austria).
- *No. of friends*: the number of friends someone has, ranging from 0 to 50; it is used as an indicator for social capital.
- *PE (perceived employability)*: answers to the question ‘Thinking about your future, how likely do you think it is that you will (ever) be employed in your desired occupation?’ – ‘Wenn Sie an Ihre Zukunft denken, für wie wahrscheinlich halten Sie es, dass Sie Ihren Wunschberuf irgendwann ausüben werden?’ on a scale from 0 (= extremely unlikely) to 10 (= extremely likely) at t0. The variable was recoded to a scale from 0 to 1 for the purpose of the analysis.
- *Self-efficacy*: due to space restrictions, we could not include a full self-efficacy item battery in our questionnaire. Hence, as an indicator for self-efficacy, we used the question ‘To what extent do the following statements apply? – I am often afraid to be unable to meet demands and expectations’ (‘Inwiefern treffen die folgenden Aussagen auf Sie zu? – Ich habe oft Angst davor, Anforderungen und Erwartungen nicht zu gerecht zu werden’), where respondents were asked to indicate their answers according to a scale from 1 (= not at all) to 4 (= completely). To calculate self-efficacy, the response categories were reversed so that higher values now indicate higher self-efficacy.

- *Work centrality*: measures the importance the respondent attaches to work, based on the question ‘How important is work in your life?’ (‘Wie wichtig ist Arbeit für Ihr Leben?’) on a scale from 0 (= completely unimportant) to 10 (= extremely important).
- *Work experience*: indicates the number of years someone has been in employment previous to t0.

Table A1. Level of formal education (at t0) for the population of young adults who became unemployed in summer 2014, the first wave survey sample, and the second wave survey sample (unweighted and weighted).

Level of formal education at t0	Reference population	Sample at t0 (unweighted)	Sample at t0 (weighted)	Sample at t1 (unweighted)	Sample at t1 (weighted)
ISCED 0-2	36.6%	35.8%	36.6%	29.3%	32.4%
ISCED 3B	31.3%	32.4%	31.3%	29.0%	31.1%
ISCED 3A-4	19.1%	19.6%	19.1%	24.4%	22.0%
ISCED 5-6	13.0%	12.2%	13.0%	17.3%	14.5%
	100%	100%	100%	100%	100%

Note: The weights for the t0 survey are based on the distribution of education (in addition to gender and age) in the population of young unemployed. Therefore the distribution in the weighted t0 sample equals the distribution in the population. The distribution in the unweighted t1 sample shows that the re-interview rate was higher among individuals with higher levels of education. This is largely corrected for when using t1 weights (see last column), but not completely, as the t1 weights are based on a wide range of factors.
